

Question I.  $(X, \mathcal{F})$  is a statistical model. <sup>data</sup>

(a) What is meant by saying  $Y = Y(x)$  is a "complete" data reduction?

Usually in our course, when  $x$  was iid. real data from a nonparametric family, the order statistics were not only sufficient but complete too. This is not always so however; the argument we used does not extend to all nonparametric families.

(b) Explain which of the following families of parent distributions on  $\mathbb{R}$  lead to completeness of the order statistics  $(X_{(1)}, \dots, X_{(n)})$  in iid. sampling. It is possible that your answers may depend on the sample size  $n$ .

(i) {continuous symmetric distributions with known center of symmetry  $\theta_0$  }.

(ii) {continuous distributions with known unique median  $\theta_0$  }.

(iii) {continuous distributions with a center of symmetry }.

Question II.  $U_1, \dots, U_n \sim \text{iid unif}[\theta-1, \theta]$ ;  $\theta \in \mathbb{R}$ ;  $n \geq 2$

(a) Explain whether this is a location family; what about a scale family.

(b) Show that  $(U_{(1)}, U_{(n)})$  is sufficient but not complete.

(c) Show that  $(U_{(1)} + U_{(n)})/2$  is not sufficient.

(d) Show that  $\bar{U} + \frac{1}{2}$  is not UMVUE for  $\theta$ .

Question III

(a) Define what is meant by a least-favorable sequence of priors  $(\Lambda_m)$ .

(b) Prove the following (familiar) theorem. (The loss function is fixed.)

"Let  $(\Lambda_m)$  be a sequence of priors with corresponding Bayes risks of their Bayes rules  $r_m \rightarrow r$ . Let  $\delta$  be an estimator with  $\sup_{\theta} R_{\theta}(\delta) = r$ ; then  $\delta$  is minimax." [Also  $(\Lambda_m)$  is least-favorable, but no need to prove that.]

We used this theorem to prove minimaxity of  $\bar{X}$  when  $X_1, \dots, X_n$  iid  $N(\mu, \sigma^2)$  with squared-error loss. The proof involved an artificiality in that we needed to restrict the parameter space by bounding  $\sigma^2$ .

(c) Why?

(d) Show with a modified loss function  $L(d, \mu) = \frac{(d-\mu)^2}{\sigma^2}$ ,

the need for that artificiality goes away, and show, using a small modification of the argument we saw, that  $\bar{X}$  is once again minimax.

Question IV  $X_1, \dots, X_n$  iid  $f_{\theta}$ :

(a) Find the AR(LL)E of the mean to the median for this problem

New change  $f_{\theta}$ :

- (b) Show that the median is no longer  $\sqrt{n}$ -consistent.
- (c) What is its consistency rate?
- (d) What is its weak limit (limiting distribution) (with suitable re-scaling)?
- (e) Which is the asymptotically preferable estimator now: the sample mean or the sample median?

Question V. Consider a regular one-parameter likelihood problem for estimating  $\theta \in \mathbb{R}^1$ .

- (a) State the theorem on efficient likelihood estimation (ELE). (No need to spell out the regularity conditions precisely.)
- (b) Explain briefly and without technicality how it can happen that the sequence of ELE's may not be observable (i.e. statistics).
- (c) Prove that if there is a consistent estimator  $\delta_n$  for the target  $\theta$ , and you pick the root  $\hat{\theta}_n$  (from the root set of the likelihood equation) closest to  $\delta_n$ , then  $(\hat{\theta}_n)$  is an ELE which is observable.

**Problem 1.** Let  $X_1, \dots, X_n$  be i.i.d. from the gamma distribution  $\Gamma(g, b)$ , which has density

$$f(x) = C(g, b)x^{g-1}e^{-x/b}, \quad x > 0,$$

where  $C(g, b)$  is a normalizing constant. Note that  $g, b > 0$ .

Find a UMP level  $\alpha$  test (if it exists) in the following two situations:

- 10 (a)  $H : b \leq b_0$  versus  $K : b > b_0$ , and  $g$  is known.   
 10 (b)  $H : g \leq g_0$  versus  $K : g > g_0$ , and  $b$  is known.   
 Be as specific as you can.

**Problem 2.** Consider the following distributions on  $\{1, \dots, 5\}$ :

	1	2	3	4	5
$P_1$	0.3	0.2	0.3	0.1	0.1
$P_2$	0.2	0.2	0.1	0.4	0.1
$Q$	0.2	0.0	0.3	0.2	0.3

We want to test  $\{P_1, P_2\}$  versus  $Q$ .

- 5 1. Find an MP test at level  $\alpha = 0.05$ . Is it unique?   
 10 2. Find an MP test at level  $\alpha = 0.15$ . Is it unique?   
 10 3. Find an MP test at level  $\alpha = 0.50$ . Is it unique?   
 5 4. Is there a level  $\alpha$  for which the MP test not unique? Justify your answer.

Below is a plot of

$$L_\lambda(x) = \frac{Q(x)}{(1-\lambda)P_1(x) + \lambda P_2(x)}$$

Each line corresponds to  $L_\lambda(x)$  as  $\lambda$  varies from 0 to 1, for each  $x = 1, 2, 3, 4, 5$ .

Handwritten notes on the right side of the page, including a definition of a set:  $\text{Set} = \{ \dots \}$ .
